TITLE: Modeling of industrial digital controls on analog computers

SOURCE: Priborostroyeniye, no. 3, 1966, 3-6

TOPIC TAGS: automatic control design, control simulator, computer control system, automatic control equipment, analog computer, digital computer system

ABSTRACT: Digital control computers are being utilized as multichannel regulators of technological processes. The authors discuss the circuits of such a multichannel system, analog-to-digital conversion, and the difficulties encountered in the design of such systems. The difficulties involve the analytical determination of time optimal control, the tuning parameters of each channel, the influence of the level quantization on the control process, etc. Since many such problems can be studied relatively simply on analog simulators the paper presents and discusses, among others, the block diagrams of a fixator model, a control-law components model, a variable coefficient block model, and a signal level quantization block model. Some

TITLE:

On the Photocolorimetric Determination of Cobalt in Rubbers  
Using Nitroso-R-Salt

PERIODICAL:

Kauchuk i Rezina, 1959, No. 11, pp. 58-59.

TEXT:

The authors outline the principle of the photocolorimetric method for determining cobalt in rubber using nitroso-R-salt: the nitroso-R-salt forms a complex compound of reddish color, soluble in water, i.e., sodium 1-nitroso-2-naphthol-3,6-disulfonate, reacting with cobalt in a medium close to neutral or weakly alkaline. An acetate medium is the most favorable one for the formation of the complex compound. An excess acidity slows up the process of the complex compound formation. The presence of the following metals do not interfere with the cobalt determination: Al, Fe, Mn, Zn, Ca, Mg, Cu, Ni, Pb, Ti, etc. Some of these metals do not react with the nitroso-R-salt at all, such as Al, Zn, Ca, Mg, Pb, Ti. The colorimetric analysis was carried out on a ФК-М (ФЕК-М) instrument with a green light filter, so that the complex solutions of the cobalt

On the Photocolorimetric Determination of Cobalt in Rubbers Using Nitroso-R-Salt

absorb the light intensively, whereas the solution of the nitroso-R-salt hardly absorbs light at all and the colored solutions of the cobalt complex obey Beer's law. The laboratory procedure for obtaining the date (Table 1) on the optical density average values is outlined. A calibrated curve is plotted according to these data. The cobalt concentration is measured in mg/100ml. The formula for computing the cobalt content is given as: % Co =  $\frac{c \cdot 500 \cdot 100}{g \cdot 1000 \cdot n}$ , where c is the cobalt quantity found according to the

calibrated curve, in mg; g is the rubber portion, in g; 1000 the coefficient of transforming the mg to g; n is the qunatity of solution, transferred from the measuring flask with a capacity of 500 ml to a measuring flask with a capacity of 100 ml (10, 15, 25 ml). Table 2 gives the results of the cobalt determination in chemically pure compounds, in mg. If the content of cobalt

is over 0.5%, the above formula is changed to: % Co =  $\frac{c \cdot 500 \cdot 100 \cdot 100}{g \cdot 1000 \cdot 25 \cdot n}$ ,

where n is the quantity of solution transferred from solution II into a measuring flask with a 100 ml capacity for colorimetric analysis (10, 15,

25 ml). The margin of error in the cobalt determination fluctuates between - 0.0002 to + 0.0005 for a cobalt content less than 0.1 mg, and between - 0.0006 to + 0.0013 mg for a cobalt content over 0.1 mg. These results are considered satisfactory. Table 3 shows that the results obtained by the photocolorimetric method coincide with the computed values of cobalt content determination in rubber. The photocolorimetric method for determining the cobalt content in rubber using the nitroso-R-salt is highly sensitive, accurate and simple to perform. The duration of one analysis, not considering the ashing of the rubber portion, is 1.5 to 2 hours. The reagents are easily obtainable. There are 3 tables and 5 Soviet references.

TITLE: Determination of chlorine and bromine in rubber...  
Vulcanisates by Combustion (Opravleniye eticheskogo  
khlorov i bromova v vulkanizatse i vulkanizatsii sozvezhniya)  
PERIODICAL: Kauchuk i rezina, 1958, No. 1, p. 5-10 (USSR)  
ABSTRACT: Various disadvantages of the methods used at present in...  
Korshun and Chumachenko are discussed. The present  
method is based on the determination of chlorine and  
by combustion in a micro-tubular electric oven. The  
method is similar to the one described by the authors  
for the determination of sulphur in rubber which was  
described in Kauchuk i rezina, 1957, No. 1. The nitrogen-  
containing rubber or vulcanisate sample is dried and the  
combustion in the oven in an air current and the  
separated halogens absorbed in alkali in the presence  
of hydrogen peroxide; chlorides and bromides are formed.  
Vanadium pentoxide is added to the reaction mixture to  
reduce the temperature of the vulcanisate and to  
eliminate all the halogenes. The combustion is rapid

Experience in the Organization of Field Work for a Stereotopographic Survey (Opyt organizatsii polevykh rabot po stereotopograficheskoy s"yemke)

PERIODICAL: Geodeziya i kartografiya, 1959, Nr 7, p 42 (USSR)

ABSTRACT:

The author gives a short report on his working methods of stereotopographic survey carried out on a scale of 1:25000 during the field work in 1958 in an area completely covered by the Taiga with absolute spot heights of 700-750 m. He carried out the work in the section of thin forest in spring when the grass was not high. In the inaccessible regions, the work was done in summer when the moisture was lowest. Very much time was saved in determining position fixed points by resection with observation from trees. This made it unnecessary to search neighboring triangulation points situated in another area. For control, the direction on the position fixed point thus determined from the next triangulation point was observed. For the rest, the method used in the organization of work was the same as that of Nikushkina (Geodeziya i kartografiya, 1959, Nr 7, pp 43 - 44 ).

TITLE Certain Aspects of Hydromechanical Analysis of a Fluidized-bed Apparatus (Nekotorye voprosy gidromekhanicheskogo issledovaniya apparatov s kipashchim stoyem)

PERIODICAL *Tr. Mosk. nauchno-tekhn. mashinostr.* 1957, Vol 13 pp 145-158

ABSTRACT It is pointed out that technical literature published to date contains very little information on methods and procedures employed to design and analysis of fluidized-bed apparatus. It is noted that without a hydromechanical analysis of fluidized-bed apparatus in the design stage it is utterly impossible to carry out subsequent thermal technological and strength computations. It is for this reason that the author attempts to formulate a basis for methods of hydromechanical analysis of the apparatus indicated above. It is claimed that the determination of cross-sectional dimensions of a fluidized-bed apparatus reduces to the determination of numerical values of the pseudo fluidization point and the "pseudofluidization number" (a relationship between the operating free stream velocity of the gas in the

Card 1/3

SOV/124-58-10-11310

Certain Aspects of Hydromechanical Analysis of a Fluidized-bed Apparatus

device and the critical velocity at which the layer of powdered material is transformed into a pseudofluidized state). It is pointed out that the transition of a cohesionless material into a pseudofluidized state occurs only if the mass forces (weight and buoyant force) are equal to the frictional force between the gas and the surface of the passages within the layer. Computational formulae are shown. The author points out that these formulae are not sufficiently accurate and attributes this to the fact that the structural factors of cohesionless materials (effective diameter of particles in the layer, the porosity of the latter, the form factor of the interstitial passages, and the void ratio) are not yet completely known. At the present time, therefore, the pseudofluidization point may be most reliably determined by experimental means. It is claimed that the process of experimental determination of the pseudofluidization point reduces to a procedure of measuring the resistance offered by a layer of cohesionless material to the passage of a gas depending on the velocity of the latter. The arrangement of an experimental system employed for this purpose is shown. Experimental data obtained are presented in the form of functional relationships between pressure drops in a column containing a layer of cohesionless material (weighing 500 g) and the velocity of the gas in the case of four fractions of quartz sand (with particles of a mean mesh size d = 0.297, 0.27, 0.180, and 0.158 mm). A method for graphical determination of the

Card 2/3

SOV/124 58 10-11310

Certain Aspects of Hydromechanical Analysis of a Fluidized bed Apparatus

pseudofluidization point is described. The fluidized-bed state is defined as a pseudofluidization condition which is accompanied by penetration of gas through the layer (in a manner analogous to the bubbling of gas through a liquid). It is pointed out that the expansion of the fluidized layer does not conform to the constant-pressure-drop law and that for an identical value of pseudofluidization number the actual expansion of the layer is considerably smaller than calculated. Reduced porosity and coefficient of gas penetration (weight ratio of the gas stream which passes through the layer) are shown to be functions of the pseudofluidization number which was introduced earlier by the author in his dissertation [Issledovaniye mekhanizma dvizheniya gaza i tverdogo materiala vo vzyvshemom tel'e. An investigation of the Mechanism of Movement of Gas and Solid Material in a Suspended Substance. Moscow-khimi. mash. str. Moscow, 1952]. Attention is called to the connection existing between methods of computing the standard ratings of fluidized-bed equipment and analogous methods for design and analysis of bubbler units for liquid substances. In conclusion, the author emphasizes the fact that the amount of experimental data available at the present time is obviously not sufficient to permit direct employment of any methods of analysis of fluidized-bed apparatus, including the method examined above, without subsequent experimental verification. ## TITLE:

The Calculation of the Heat Exchange Surface in Apparatuses With a Fluidized Bed

## PERIODICAL:

Khimicheskoye mashinostroeniye, 1959, Nr. 5, pp. 6-9 (USSR)

## ABSTRACT:

The known methods of studying thermal properties of a fluidized bed are based mainly on stationary conditions of heat transfer. Lately, methods based on non-stationary heat conductivity have become popular (Ref. 2). These methods require considerably less time for measurements while the accuracy of determining the thermophysical constants is noticeably higher in some cases. The method of the regular process, developed by G.M. Kondratyev and his students (Ref. 3) occupies an outstanding place among these methods. It is based on the assumption that the coefficient of heat emission from a cooled body to an ambient medium is constant and that there is no internal source of heat in a body. In this case the cooling process can be divided into a stage of an irregular heat transfer process and a stage of a regular process. At the moment, when the regular process begins, the natural logarithm of the difference between the

Card 1/5

82776

SOV/184-59-5-3/17

The Calculation of the Heat Exchange Surface in Apparatuses With a Fluidized Bed

temperature of any point of the body and the temperature of the ambient medium will vary linearly in time. The gradient of the straight line describes the rate of cooling. (Formula 1). A silver ball of 10 mm. radius was used for the experimental investigation. The coefficient of heat emission of the silver ball was  $\alpha = 1.96$   $m \cdot kcal/m^2 \cdot h^{\circ}C$ . The experimental set-up for determining the coefficient of heat emission in a fluidized bed is shown in diagram, Figure 1. The fluidized bed was produced in apparatuses of 82.5 and 157 mm diameter, but no influence of the diameters on the heat transfer process was found. The ball was heated to  $800^{\circ}C$  and was immersed rapidly into the fluidized bed. The change of its temperature during the cooling process was recorded with an "ЭПП -9" (EPP-09) automatic potentiometer (speed of tape 2.665 mm/sec). The fluidized bed was kept at a temperature of  $20-30^{\circ}C$  by blowing air into it at room temperature. The electric heating furnace was equipped with a МРШНР-54 (MRSnchPR-54) keeping the temperature control within 1.5%. The error in determining the coefficient of heat emission did not exceed 10%. Quartz sand, ferrosilicon, hematite, glass balls and carborundum were used for producing the fluidized bed. Air without any preliminary treatment was used

Card 2/5

82776

SOV/184-59-5-3/17

The Calculation of the Heat Exchange Surface in Apparatuses With a Fluidized Bed

as a pseudoliquefying medium. Curves showing the cooling of the silver ball were plotted for each material at different linear air velocities in the apparatus. These curves were used for computing the graphs of the coefficients of heat emission, shown in Figure 2. These graphs show the combined influence of the physical properties of the system and the pseudoliquefying conditions on the coefficient of heat emission. Wicke (Ref. 4) and S.S. Zabrodskiy (Ref. 5 and 6) noticed a maximum on the curve of dependence of the coefficient of heat emission on the gas velocity in the apparatus. This led them to the assumption that there is one pseudoliquefying process common to all materials which is called the optimum process. The hydro-mechanical conditions of this process have not yet been established. The heat exchange in a pseudoliquefied layer has all features of an intensive convective heat exchange in which the moving particles of solid matter play the part of turbulent vortices. To prove that the criterion equation for gases  $Nu = A_1 Re^m$  (3) is also true for the optimum process (criterion  $Re_0$ ) the maximum coefficients of heat emission  $\alpha_{max}$  and the corresponding gas velocities ( $U_0$ ) (the optimum pseudoliquefaction speeds) were determined and the values of  $Nu_{max}$  and  $Re_0$  were computed. The equation  $Nu_{max} = 2R_0^{0.4}$  (4) generalizes

Card 3/5

82776

SOV/184-59-5-3/17

The Calculation of the Heat Exchange Surface in Apparatuses With a Fluidized Bed

the authors' experimental data and those of Wicke (Ref. 4), obtained by the method of the stationary heat transfer, with an accuracy of about 18%. For the process of motion of solid matter in a pseudoliquefied state the equation  $Re = BAr^u$  ( $Ar$  - Archimedes' criterion) is given. The assumption that this equation is also true for the optimum pseudoliquefaction process and that the latter is affected solely by physical properties of a system is confirmed by the graph, Figure 4, where the straight line represents the equation  $Re_0 = 0.121 Ar^{0.5}$  (5). The equation  $Nu_{max} = 0.86 Ar^{0.2}$  (6) is obtained by a combined solution of equations (4) and (5). The true coefficient of heat emission  $\alpha_t$  will differ from that computed by the equation (6) depending on the shape and position of the heat exchange surface. To account for these factors a coefficient  $K = \frac{\alpha_t}{\alpha_{max}}$  is introduced.

The experimental data available do not suggest any definite values of  $K$ .  $K = 0.8-0.9$  can be used for preliminary calculations of industrial apparatuses while  $K = 0.5-0.8$  is used for small laboratory models. The value of  $\alpha_{max}$ , derived from equation (6) is in good agreement with the empirical equation of S.S. Zabrodskiy (Ref. 6). However, Zabrodskiy's equation does not take into account the effects of temperature and pressure on the properties of gas. The

TITLE: An Installation for Oxidizing Naphthalene Into Phthalic Anhydride

PERIODICAL: Byulleten' izobreteniy, 1959, Nr 9, p 14 (USSR)

ABSTRACT: Class 12g, 4<sub>Q2</sub>. Nr 119521 (597441 of 15 April 1958). The installation is for oxidizing naphthalene into phthalic anhydride on a pseudo-boiling powder catalyzer, and consists of a cylindrical reactor partitioned horizontally, and a detachable pneumatic lift for circulating the catalyzer. To intensify the process, the partitions in the reactor have holes in them so that the gas and the catalyzer can flow in opposite directions without mixing between the sections, while the pneumatic transport device is made in the form of a vertical tube with a nozzle through which vertical cooling pipes pass.

TITLE: Selecting the number of digits for output devices of a multichannel digital controller

SOURCE: Friborostroyeniye, no. 2, 1965, 1-3

TOPIC TAGS: digital controller, digital process control, automatic control, automatic control design, automatic control system, automatic control theory

ABSTRACT: Using a model which simulated a digital process control, the effect of level quantization of the controlling signal upon the control process was evaluated; also, a minimum number of digits in the control-computer output which still did not impair the quality of control was determined. The investigation was performed on a "Kataliz" analog computer to which a set of delay lines was

Card 1/2

L 38589-65  
ACCESSION NR: AP5005932

added; the signal was level-quantized by a nonlinear NB-5 unit, and the number of stops at its output showed the number of digits. To reduce the amplitude of sustained cycling that accompanied a few-digit system, the control-parameter algorithm was changed; instead of calculating the control-organ position, its speed was calculated; a stepping motor was used as an actuating device. A linear nonisometric-digit code conversion of the control signal (greater control action for greater errors) made possible a high-static-accuracy system with a few digits in the output devices. "O. G. Druzhinin took part in the simulation of digital automatic-control systems." Orig. art. has: 5 figures, 5 formulas, and 2 tables.

TITLE: Mechanical Properties of Textolite and Getinax at Low Temperatures

PERIODICAL: Kislorod, 1959, Nr 5, pp 26 - 28 (USSR)

ABSTRACT: The above materials (tissue- and paperlike stratified materials) have a low heat conduction coefficient, and gain more and more in importance owing to their mechanical properties in the production of details of low-temperature apparatus. The mechanical properties of these substances at low temperatures are not yet known. The Laboratory of Metal Investigations of the VNIIKIMASH, therefore, made investigations of the substances at low and normal temperatures. Textolite of the PT(GOST 5-52) type, and getinax of the V(GOST 2718-54) type were tested according to the method GOST 4670-49. The samples were given a special form in examinations for elasticity which made them break in the midale (Fig 1). The investigation results are compiled in table 1. Examinations for compression were made on prismatic samples; data are given in table 2. Hence it appears that both substances have better mechanical properties at low temperatures. Textolite, for instance, proved

Card 1/2

✓

Mechanical Properties of Textolite and Getinax at Low Temperatures SCV/63-54-17-1

to be considerably more solid at a tension test at low temperatures whereas getinax was more stable in a compression test. Textolite did not solidify to such an extent as getinax. The following was found in investigations of the substances at their cleavage along stratification: textolite showed cracks at random while getinax exactly broke into halves or into few flat plates (Table 3). Further, the resistance to shock was determined. Both materials proved to be equally stable against shock (Table 4). At low temperatures, the resistance to shock decreased more in the case of textolite than of getinax (Fig 3). The hardness of the stratified material was determined according to the method by NIIFLASTMASS. Both materials reached, at a temperature of -196°, the double degree of hardness (Table 5) in contrast to that attained at room temperature. There are 3 figures and 5 tables.

TITLE: On the possibility of increasing the toughness of ordinary structural steel at low temperatures

PERIODICAL: Referativnyy zhurnal, Mashinostroyeniye, no. 4, 1962, 15, No. 4A104 ("Tr. Vses. n.-i. in-ta kislorodn. mashinostr.", Vol. no. 3, 140 - 143)

TEXT: Research work has been carried out to determine the possibilities of using ordinary structural steel at low temperatures (-183°C). The author presents the mechanical properties of Cromansil-type steels (25X7C [25KhGS], 35X7C [30KhGS]) at a temperature of -183°C. 25KhGS grade steel hardened at 880°C and high-tempered at 700°C for one hour showed the following parameters at -183°C:  $\sigma_b = 113$ ,  $\sigma_s = 96$  kg/mm<sup>2</sup>,  $\delta = 50\%$ ,  $a_k = 4.1$  kgm/cm<sup>2</sup>. It is shown that it is possible to considerably increase  $a_k$  of ordinary structural steels by a careful selection of the heat-treatment conditions.

34. Effect of neutralization and crystallization in reducing h.v.  
losses in glass. G. T. SKANAVI AND R. MARTYUSHOV. J. Techn. Phys.  
U.S.S.R., 9, 11, pp. 1024-1031, 1939. In Russian.—The neutralizing  
effect appears at substantial concentrations of alkaline oxides in the glass.  
Obviously it is related to a steep increase of  $\tan \delta$  with the concentration of  
alkali oxide in twin glasses. As, on the other hand, it is observed at room  
temperature as well as at higher temperatures, a connection with the time  
of relaxation of the dielectric losses in the glass is evident. In the case of  
low concentrations the potential barrier hindering the mobility of the free  
ions does not depend on the ionic concentration. Therefore the relation  
between  $\tan \delta$  and the concentration is not of an exponential character.  
As a possible explanation of these conditions mutual reactions between  
the ions taking place in highly concentrated bulk of these could be assumed.  
The experiment shows that  $\tan \delta$  of the temperature curves and curves of  
electric conductivity for simple glasses is diminishing with increasing  
concentration of oxides.

Resistors; design, principles of technology and parameters (Rezistory; konstruktsii, osnovy tekhnologii i parametry) Moscow, Izd-vo "Energiya", 1966. 215 p. illus., biblio. 13,000 copies printed.

TOPIC TAGS: resistor, carbon resistor, ~~semiconductor resistor~~, semiconductor resistor, composition resistor, metal oxide resistor, metal film ~~filament~~ filament wound construction

PURPOSE AND COVERAGE: This book is intended for engineers and technicians working in the field of resistor design or concerned with their use in various equipment. It may also be used as a textbook for students of technical schools of higher education. The book examines the fundamentals of designing, peculiarities of the technology, and basic parameters of carbon, metal-film, composition, wire-wound, and semiconductor resistors. Primary attention is devoted to modern types of resistors developed recently by domestic industry. Problems of developing miniature resistors are examined, and the prospects for using new materials for developing resistors with good electrical parameters and small size are analyzed. There are 102 references, 64 of which are Soviet.

G. I. Skanavi

PERIODICAL: Elektrichestvo, 1960, Nr 4, p 94 (USSR)

TEXT: This is an obituary for Professor Georgiy Ivanovich Skanavi, scientist in the field of physics of dielectrics, who died on November 11, 1959. He graduated from the fiziko-mekhanicheskiy fakultet Leningradskogo politekhnicheskogo instituta (Department of Physics and Mechanics of the Leningrad Polytechnic Institute), and then worked at the "Elektrosila" Works in Leningrad. From 1935 to 1938 he worked at the Nauchno-issledovatel'skiy institut (Scientific Research Institute) as a team leader, and later as director of a scientific department. The mass production of ceramic radiotechnical capacitors was started in one of the works on his initiative and with his direct cooperation. He took his doctor's degree in 1946, and then became a professor. From 1940 until his death, he worked at the Fizicheskiy Institut Akademii nauk SSSR (Physics Institute of the AS USSR), first under the direction of B. M. Vul, ✓

TITLE: Heating of articles in a fluidized bed

SOURCE: Metallovedeniye i termicheskaya obrabotka metallov, no. 12, 1964, 28-30

TOPIC TAGS: fluidized bed, heat treatment, high temperature heating

ABSTRACT: The purpose of this investigation was to compare the heating capacity of a fluidized bed and other media for heat treatment and to study the mechanism of high-temperature heating in a fluidized bed. A device was designed for this purpose (see Fig. 1 of the Enclosure) in which a layer of granular material was placed on a metal grating. The fluidized layer was heated by two electric heaters. Air, passed through the lower heater, was heated to a given temperature and delivered to a cylinder with the granular material. At a gas velocity exceeding the critical, the layer of granular material passed into a pseudo-liquefied state. To compensate for heat losses into the ambient medium outside of the fluidized state, an electric heater was installed at the level of the fluidized bed. The preassigned temperature in the fluidized bed was maintained by temperature regulators through a thermocouple submerged in a fluidized bed. Quartz sand was used as the granular material, grain size 0.256 mm. A silver ball, 20 mm in

L-20973-65  
ACCESSION NR: AP5900935

diameter, was submerged into the bed. In the center of the ball was the hot junction of a chromelalumel thermocouple. The heating curves were recorded by an electronic potentiometer. Two rotameters measured the consumption of air. Heat transfer between the pseudo-liquefied medium and the ball surface was studied at various gas velocities and fluidized bed temperatures of 100-800C. With an increase of the bed temperature from 100 to 800C the value of the maximal heat-transfer coefficient increased from 410 to 560 W/m<sup>2</sup>. deg. With an increase in gas velocity the heat-transfer coefficient at first rapidly increases, then smoothly falls off. It was found that the fluidized bed can replace heating media that are used in heat-treatment departments and that the rate of heating in the fluidized bed can be controlled and is thus amenable to program-controlled heating. Orig. art. has: 3 figures.

2815. EPIDEMIOLOGICAL SIGNIFICANCE OF VARIOUS SPECIES OF PHLEBOTOMUS IN GEORGIA (Russian text) - Matvashvili G. M. - MED. PARAZIT. I PARAZIT. BOL. 1958. 27/5 (591-593)

In the eastern part of the Georgian Soviet Socialist Republic, 11 species and varieties of Phlebotomus are encountered. These belong to 4 groups: Ph. papatasii, Ph. sergenti, Ph. major and Ph. minutus. In rare cases phlebotomi were found in a village of Western Georgia, on the western slopes of the Suram mountain-ridge. They are encountered both in various residential premises and under natural conditions - in caves, holes, ruins of ancient monasteries, fortresses, etc. The spreading of individual species of Phlebotomus is characterized by their strict limitation to certain foci. By comparing the map showing the distribution of Phlebotomus with that of visceral leishmaniasis, Borovsky's disease (cutaneous leishmaniasis) and of pappataci fever, it becomes evident that distinct species of mosquitoes correspond to the foci of these diseases. In the area of distribution of visceral leishmaniasis, for the most part (up to 600 m. above sea level) or exclusively (over 600 m. and up to 1240 m. above sea level) Ph. chinensis and Ph. kandeliaki, are encountered, which should be considered as the carriers of this disease. Proceeding westward within the boundaries of Eastern Georgia, the proportion of Ph. chinensis and Ph. kandeliaki gradually diminishes, and to the west of Tbilisi, along the valley of the Kura river, Ph. caucasicus begins to dominate numerically and should be regarded as the carrier of Borovsky's disease. Ph. papatasii - the carrier of pappataci fever - is found in the area of visceral leishmaniasis in extremely small numbers (exclusively at altitudes of up to 600 m.), while in the foci of Borovsky's disease it occupies 2nd place. Pappataci fever is encountered in the area of Borovsky's disease, but is absent in that of visceral leishmaniasis. The peculiar distribution of sand flies, according to their species and to the diseases carried by them, could be explained by the natural and topographical features of the foci.

Central Megreliya forms a low plateau intersected  
by several rivers. Clastic cavern formations be-  
long to a Neogenic stratum (about 550 sq km) of  
conglomerates and sandstone cemented with calcareous  
matter. They are a good example of the relation  
between cave formation and the development of ~~me-~~-  
rane erosion. Separate craters and pits are
